The Institute for Social and Economic Change,  
Bangalore

*Institute for Social and Economic Change (ISEC) is engaged in interdisciplinary research in analytical and applied areas of the social sciences, encompassing diverse aspects of development. ISEC works with central, state and local governments as well as international agencies by undertaking systematic studies of resource potential, identifying factors influencing growth and examining measures for reducing poverty. The thrust areas of research include state and local economic policies, issues relating to sociological and demographic transition, environmental issues and fiscal, administrative and political decentralization and governance. It pursues fruitful contacts with other institutions and scholars devoted to social science research through collaborative research programmes, seminars, etc.*

*The Working Paper Series provides an opportunity for ISEC faculty, visiting fellows and PhD scholars to discuss their ideas and research work before publication and to get feedback from their peer group. Papers selected for publication in the series present empirical analyses and generally deal with wider issues of public policy at a sectoral, regional or national level. These working papers undergo review but typically do not present final research results, and constitute works in progress.*

# FARMERS' PERCEPTION ON RISK AND MANAGEMENT STRATEGIES IN MAHANADI RIVER BASIN IN ODISHA: AN ECONOMIC ANALYSIS

a anti Ma a Na ak an A V Manjunatha

## Abstract

Using primary data from Mahanadi River Basin of Odisha, the present study examines the risk perceptions, management strategies and their relationship with farm and farmer characteristics. A total of 120 farmers were interviewed from three districts, namely, Sonepur, Boudh and Kendrapada, which are in upper, middle and lower region of Mahanadi River. Drought was perceived as the most important source of risk in upper Mahanadi region, inadequate government support, including crop insurance, in middle Mahanadi region and flood in lower Mahanadi region. The important risk management strategies followed by upper Mahanadi region farmers was varietal diversification of the same crop specifically paddy while it is crop diversification in middle mixed cropping and lower Mahanadi region. The result of Multiple regression analysis shows that risk perception of the farmers of these three regions were influenced by social groups, off farm income, ratio of earning member to the household size, farm size, land ownership status and government support. The regression results of management strategies are almost similar with the results of risk perception, social group, ratio earning member to the household size, land ownership status, age, off farm income and farm size have a significant influence on the management strategies across the three regions.

**Keywords** Perceptions of risk, Risk Management Strategies, Farmers, Multivariate Analysis, Odisha, India

## Introduction

The concept of risk and uncertainty is all about future expectations, which are associated with the probability of unexpected loss (Dallas, 1997). Besides, it is widely viewed as a complicated factor which influences decision making under uncertain conditions and its outcome in the future (Hardaker, 2000). Risk and uncertainty are more prominent in agriculture than in industry. Agriculture is exposed to several types of risks, starting from the field to the market. A farmer must take decision under different types of vulnerable and uncertain situations. These vulnerabilities arise due to natural hazards, market fluctuations, social uncertainties, State actions and wars (Harris, 1997). Therefore, most of the farmers endow some extra time and capital to develop appropriate adaptive measures to tackle these risks.

Agricultural risks in developing countries mainly occur due to the difference in geographical regions, regular natural hazards, erratic climatic condition, seasonality in farm production, pest and diseases, fluctuating market demand for agricultural commodities, fluctuation in input and output price, inadequate financial support in terms of credit and insurance during requirement by the government (Akhtar *et al.*, 2000). These risks directly affect the agricultural production which further affects the income and the livelihood of farmers. Since agriculture is the main source of income for farmers, it is

Assistant Professor, Centre for Ecological Economics and Natural Resources (CENR), Institute for Social and Economic Change (ISEC), Bengaluru

very important to identify the risks faced by farmers and their management strategies Drollette, , Akhtar *et al*,

India is the second largest populous country in the world Maintaining food security for the huge population is the main concern of the country In such a scenario, if farmers behave as risk averse, then the resource will be misallocated and it will further reduce the overall welfare of the society On the other hand, if farmers behave as risk neutral, then their production decisions would affect the expected marginal productivity Akhtar *et al*, Therefore, the Government should understand the exact situation and implement appropriate policies or programmes to increase farmers risk taking capacity In this context, it is very important to understand the sources of agricultural risk that farmers face Understanding these sources of risk will help the farmers in taking appropriate management strategies For examining farmers behaviour in uncertainty, it is necessary to know farmers perception towards risk Lucas and Pabuayon, Perceptions of sources of risk act as a starting point for taking decisions on risk management Perception towards risk also influences the investment and business decisions under uncertainty Akcaoz and Ozkan, Similarly, in agriculture sector, risk perception influences farmers risk attitude and management decisions insen *et al*, A farmer takes decisions according to his perception towards risks eber and see,

This study examines farmers perception towards agricultural risks, management strategies and their relationship with socio economic characteristics Risk perception and management strategies significantly differ on the basis of age, years of education Kammar and Bhagat, Bishu *et al*, number of earning members Ayinde, , social group Ahsan, on religion , land ownership status Flaten *et al*, , depending on other farm activities like dairy and poultry Le Bihan *et al*, , farming experience Lucas and Pabuayon, , off farm income Flaten *et al*, Bardhan *et al*, Ahsan, I bal *et al*, Asravor, , farm size Feder, I bal *et al*, , distance to market Akhtar *et al*, , market information Asravor, , bank loan Lucas and Pabuayon, and government support Bardhan *et al*, Amaefula *et al*, These studies have examined the risk perceptions, management strategies and their relationship with socio economic characteristics of agricultural, livestock, and fishery farmers These studies showed mixed either positive or negative results on socio economic characteristics on risk perceptions and management strategies relationship Status of this relationship varies due to difference in social, demographic and economic features Nevertheless, these studies provide valuable insight to the policy makers and farmers

In the Indian context, such studies on agricultural risks are limited Bardhan *et al*/ Murthy *et al*/ Ramaswami *et al*/ Panneerselvam *et al*/ Singh *et al* are recent studies in India These studies mostly focussed on climate related risk and their adoption strategies Moreover, these studies have not investigated the issues of production, market and financial risk in detail, with respect to India Remaining risks, like market and financial aspects, are very crucial in developing countries Studies on these aspects are very meagre in the context of India Hence, an in depth study on financial and market risk in the context of developing country is crucial

This paper attempts to study the risk perception of farmers from Mahanadi river basin of Odisha, India It further examines the determinants of risks and the risk management strategies

followed by them. The findings of this study are expected to help the government in developing better policies and thereby facilitate the farmers in taking appropriate management strategies under various uncertain situations. The findings of this study will also aid policy makers to fine tune government policies and programs towards management of agricultural risks in Odisha State of India.

The rest of the paper is organised as follows: section two presents the theoretical framework of the study, the third section discusses the methodology, the fourth section explains the results and the fifth section concludes the paper.

## **Background about Odisha Agriculture**

Odisha is a state of India where about 65 per cent of the population are agriculturalist and the contribution of the sector to the Gross State Domestic Product (GSDP) is only 12 per cent (GoO, 2014). This is because of the low per capita income in the agricultural sector. The main cause for low production and per capita income in this sector is due to frequent occurrence of natural hazards like cyclones, flash floods, drought and heat waves etc. (Chittibabu *et al.*, 2011; Patnaik *et al.*, 2012; Bahinipati, Patnaik, 2013). Natural disasters are common in Odisha. It has been recorded that over 100 years to 200 years were affected by natural hazards (GoO, 2014). The main reason for these calamities is heavy or scanty rainfall. Rainfall plays a vital role among the agricultural producers because most of them are rainfed cultivators. These cultivators fully depend on nature starting from sowing to packaging. It is well known that occurrence of rainfall is very uncertain, therefore the production and income of a farmer is also uncertain. This uncertainty not only encourages production risk but also their income risk, market risk and financial risks. In order to tackle these risks and to encourage the farm producers for more agricultural investments, both state and central governments have implemented many schemes like crop insurance (Pradhan Mantri Phasal Bima Yojna), subsidies in the form of cash and kind (e.g. seed, agricultural equipment, fertilizer, irrigation credit, power subsidies etc.), crop loss compensation, training programmes, pest management plan, soil health management plan etc. Likewise, farmers from the state have also taken various coping up strategies like financial management, on farm management, off farm management etc. in the highly vulnerable regions of Odisha (Roy *et al.*, 2011; Bahinipati, Venkatachalam, 2012). According to Bahinipati (2013) farmers from the flood prone region adopt risk management strategies like flood and salt tolerant traditional paddy seeds (like Padma, Bhaluki and Raspanjar etc.), re-cultivation of seedling and re-planting, mixed paddy (both traditional and V-seeds) cropping, crop diversification, pest and disease management, soil conservation through soil tillage or using gypsum etc. techniques and land holiday (keeping a piece of land fallow). Further, Patnaik *et al.* (2012) reported the use of credit or borrowing, selling household assets and livestock, and receiving remittances from migrant members were the most adopted management strategies of the coastal region farmers from Odisha.

## **Theoretical Framework**

Expected utility theory is commonly used for the purpose of descriptive and normative aspects in the decision making analyses by economists. It is widely known as normative model, where the decision maker is assumed to be fully rational and always tries for the highest expected outcome. (Schoemaker

and Evershey, This theory, derived from expected utility hypothesis, depicts how a person should make decisions under uncertainty. Pennings and Smidts This theory depends on the probability and consequences of an outcome while an individual generally takes decision according to the probability of an outcome.

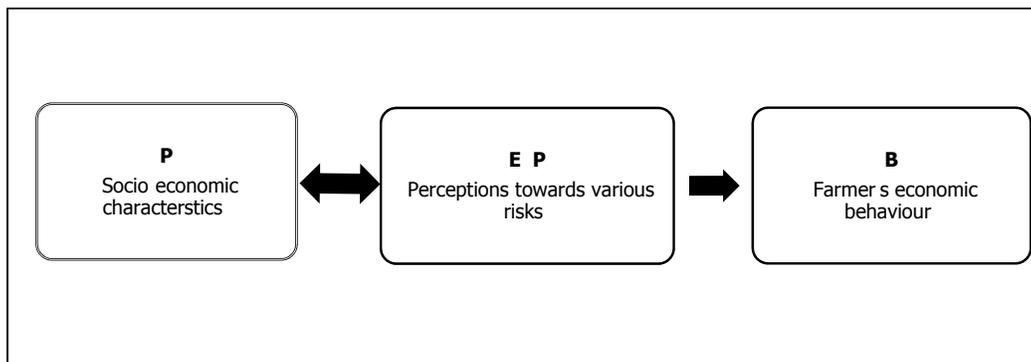

According to this theory, the results of risk attitude analysis using different procedures should come with identical results. However, empirical analysis suggested unidentical results across methods. MacCrimmon and Ehrung In the case of probability outcome estimation, individuals do use heuristics (mental shortcuts) rather than using mathematical formula like Bayes' rule. Tversky and Kahneman, Lichtenstein and Slovic found a fundamental disparity between gambling decisions and lottery choices. Hille, Kirchler, Maciejovsky and Eber suggested that certainty equivalents and binary lottery choices elicitation methods were poorly correlated with each other. Because of which expected utility theory was highly criticised on descriptive grounds by many economists since it had a problem in explaining the observed behaviour (risk perceptions) of an individual. Kahneman and Tversky, Allais, MacCrimmon and Ehrung Further findings from the experimental method depicted that an individual perceives differently towards same possible outcomes of an event according to his/her subjective judgement.

Perceptions of an individual's decision is a subjective phenomenon because it is associated with unknown factors in it. MacCrimmon and Ehrung Perceptions of an individual remain same (subjective) in the case of known risk factors because of its personalised nature of probability of loss determinations. There are some decision making behaviours which cannot be explained by expected utility model. For solving this ambiguity, economists like Kahneman and Tversky, Shapira, Sitkin and Pablo proposed subjective aspect of decision making approach. For this subjective decision making approach, understanding risk perceptions of an individual and its determining factors is very essential because of its significant impact on decision making behaviour. Rabin and Thaler

This study uses van Raaij's descriptive model, where economic behaviour of an individual with subjective goal of well-being in mind is determined by perceptions of an individual about economic environment. Lien *et al*, This model shows the impact of farm and farmers characteristics (i.e. age, education, income level, farm size) on farmers' perceptions towards risk. It also examines the combined impact of farm/farmers characteristics and perceptions towards risks on the economic behaviour of farmers (i.e. risk management strategies). Many economists like Flaten *et al*, Bardhan *et al*, Ahsan, Ibal *et al*, Asravor, used this model to show the influence of farm and farmers characteristics, risk perceptions on risk management strategies and came out with interesting results. This paper also attempts to explain the relationship between farm/farmer characteristics, risk perceptions and management strategies by using van Raaij's model. Figure illustrates the modified version of Van Raaij's economic-psychological model. This figure only uses those variables which are relevant for the study. However, the other variables of Van Raaij's model have been excluded from this study. In this figure, P refers to personal characteristics of socio-economics, P refers to the business environment as perceived by the farm entrepreneurs, B refers to economic behaviour of farmers. The causal link is denoted by  $P \square P$  which shows the impact of

socio economic characteristics on perceptions of farm entrepreneur P Again, the causal link denoted by P → B shows how personal characteristics and perception towards risk affects farmers economic behaviour like investment decisions and risk management strategies

**Figure 1: Van Raai 's Model of Economic-Psychological Relationships**

## Materials and Methods

### Summary of Location

Odisha is a state which is in the eastern part of India. It has a land area of 1,50,000 square kilometres and is broadly divided into four geographical regions, namely, Northern Plateau, Central River Basins, Western Hills and Coastal Plains based on geological and climatic conditions. This State has a long coastline of 1,500 kilometres and because of this, it faces multiple natural disasters. Annual reports on natural calamities, GoO stated that western districts are prone to droughts, the coastal districts are prone to high floods and cyclones in the state. Odisha has experienced cyclones and floods for about 50 years between 1940 and 1990. The State also faces other natural disasters like earthquake, heat waves and fire accidents. The Annual Reports on Natural Calamities ARNC GoO found that about 10 per cent of the State is disaster prone. Agriculture is the principal source of livelihood for the people of Odisha and rainfall is the main source of water for agriculture. Odisha has been selected as the study location because of its frequent flood situations. Annual reports on natural calamities GoO, show that Odisha has experienced flood every year since 1950. Flood in coastal part is mainly brought about by the five important rivers, namely, the Subarnarekha, Burha Balanga, Baitarani, Brahmani and Mahanadi and their tributaries in Odisha. Besides, drought is a common feature mostly in western parts of Odisha which has been experienced in almost every alternate year.

### Data

The present study uses primary and secondary data. The secondary data on farmers were collected from district agricultural offices while the primary data were collected through structured questionnaire and in depth interview. Sample households were selected from three flood affected districts of Odisha, namely, Sonapur, Boudh and Kendrapada which are in upper, middle and lower region of the Mahanadi River respectively. This paper analyses the data on farmers residing in these three regions.

A seventeen page questionnaire was prepared which contained question related to farm and farmers characteristics, farmers perceptions towards production, market and financial risks and farmers perception towards various management strategies. The questionnaire related to farm farmers characteristics are mainly dichotomous questions which contains yes or no type responses. The questions related to risk perceptions and management strategies contain close ended questions which were in the form of five point Likert scale type. The questionnaire was pre tested and refined according to the suggestions and comments given by the farmers during a pilot survey.

Information on the sampled farmers were collected from Special Relief Commissioner SRC, Odisha, where they registered their name for availing crop damage compensation and reliefs from government. Secondary data related to their farm, cropping details, receipt of government support was collected from district agricultural offices Sonepur, Boudh and Kendrapada.

### **Sample**

A multi stage random sampling technique has been followed for selecting districts, blocks, Gram Panchayats, villages and respondents in this study. According to flood data, nearly districts of Odisha were affected by flood ARNC GoO. In the first stage, three districts out of the flood affected districts have been selected. In the second stage, three flood affected blocks were randomly chosen from these districts. In the third stage, nine revenue villages from each block were selected randomly. In the final stage, to respondents were interviewed from each of these villages. Primary data was collected from a total sample size of , out of this, farmers were from upper region, farmers from middle region and farmers from lower region. The primary data was collected for the agriculture year. Farmers of the regions were very cooperative and friendly. Before conducting the survey, I visited the sampled villages and built personal relationship with the respondents so that it can be helpful during actual interview.

### **Analytical Techniques**

Compilation and analysis of data has been carried using descriptive statistics and factor analysis. Information on socio economic characteristics have been analysed by using descriptive statistics table. Farmers perceptions towards risk and perceptions of management strategies were analysed through factor analysis.

Factor analysis has been employed to find the reduced number of factors by summarising the information. As a rule of thumb, only factors with latent root criterion eigenvalue greater than one has been considered in this study. Orthogonal varimax rotation was implemented in order to minimize the number of variables that have high loadings on each factor to obtain factor solutions that were easier to interpret. In addition, Kaiser Meyer Olkin KMO measures sampling adequacy was used to check the factorability of the correlation matrices. The KMO value varies from zero to one here, one indicates that each variable is perfectly predicted without error by the other variables. KMO result of or greater was recommended in this study. Stevens *et al*,

Multiple regression analysis has been used to examine the relation between socio economic characteristics, perceptions of risk and risk management strategies. Before running multiple regressions,

a preliminary analysis was carried out for all the multiple regressions to verify that there is no violation of assumptions. Normality, heteroscedasticity and multicollinearity test were conducted to ensure the appropriateness of the model. No multicollinearity and heteroscedasticity problems were detected.

## **Results and Discussion**

### **Socio-economic characteristics**

Table shows the descriptive statistics on socio economic features of sample farmers. They are classified in terms of age, years of education, ratio of earning members to the total family size, social groups, years of experience, farm size, off farm income, ownership of the land, other farm activities, bank loan, outstanding debt in bank, government support, market distance and market information. This information is used as determinants of perception of sources of risk and management strategy components obtained from factor analysis using the multiple regression analysis. Average ages of the farmers of the three regions upper, middle and lower were , and years, respectively. Experience in agriculture of the farmers of three regions was , and years, respectively. The ratio of earning members to family size was more than per cent in all the three regions. Average size of the farm household in upper region was about acres, acres in the middle region and acres in lower region. It is to note that nearly per cent of farmers from upper region, per cent from middle region and per cent from lower region belong to general and other backward categories (OBC).

Average years of education of the farmers of three regions were , and years, respectively. About Rs , income generated from off farm activities in upper region, Rs , in middle and Rs , in lower region annually. Nearly to per cent farmers were depending upon bank loans in the three regions. Nearly per cent of upper region farmers opined that they had outstanding loan in the bank, whereas farmers from middle and lower regions opined they also had outstanding loan in the banks. Nearly per cent of the farmers from upper and middle regions depend on government support like irrigation facilities and input subsidies, while per cent farmers from the lower region depends on government support. Average distance to main market from the village for three regions was approximately to kilometres. Nearly per cent of the farmers from three regions avail information about the market from friends, relatives and known retailers.

### Farmers perceptions towards various types of risk

The result of factor analysis on farmers perception towards various risk for upper, middle and lower region were shown in table I, II and III see Appendix Table contains both mean values and factor loadings The mean values were in decreasing order and the factor loadings are above the threshold level i.e. greater than 50 per cent exploratory factor analysis FA has been used to reduce the variables into smaller number of factors Six to seven major factors were obtained from sources of risk that were identified from farmers of upper, middle and lower region These factors explain about 60 per cent, 55 per cent, middle and 45 per cent lower of the total variance These factors were production risk, credit risk, market risk, input cost, land risk, flood risk, catastrophe and cashlessness From among these factors, credit risk contains higher loading in upper and lower region whereas production risk for middle region

It can be clearly seen from table I See Appendix that drought and shortage of cash on hand were the most important sources of risk in the upper region whereas the least important factors were product quality requirement of traders In the middle region, inadequate governmental

support, specifically crop insurance, was the most important and change in land prices was the least important source of risk Table II, See Appendix For the lower region, water logging and inadequate government support specifically crop insurance were perceived as most important and change in land price as least important sources of risk Table III, See Appendix

In upper Mahanadi region, factor can be named as credit risk It contained five variables which are related to finance issues This factor explained about per cent of the total variance Input cost Factor contains six input and its cost related variables which was clearly shown in table I See Appendix All the variables were positively related to this factor Factor can be summarised as market risk because it contains five market risk related variables Factor can be named as flood risk which includes the high factor loading of flood related variables Table I, See Appendix Cashlessness Factor contains three variables, namely, shortage of cash on hand, lack of savings, inadequate government support, including crop insurance, which had a positive relation with it Factor production risk had a positive relation with the yield influenced variables, namely, drought, pest diseases, unfavorable weather condition during crop cycle and weeds

In the middle Mahanadi region production risk Factor contained nine variables, namely sand casting, water logging, drought, soil erosion, unfavourable weather condition during crop cycle, surface runoff, pests and diseases, weeds and sediment loading, which had a positive relation with it Table II, see Appendix This factor explains about percent out of total variance For this region, farmers production risk was main source of risk Factor was named as credit risk which contains five finance related risk variables Market risk factor had a positive relation with product quality requirement of traders, lack of alternate markets and transportation problem, which were market related risk variables Factor can be summarized as input cost It contains four input related variables Factor cashlessness contains three variables whose values were greater than Land risk factor contains two land related variables such as landlessness of family member within joint farm household and changes in land prices

Table III see Appendix represents the varimax rotated factor loadings of risk source in lower Mahanadi region farmers Credit risk factor in the table III contains five variables with higher scores namely lack access to institutional credit, indebtedness, credit ceiling based on land, delay in access to institutional credit and varying institutional interest rates Finance related risk was very high in this region due to unavailability of financial institutions and poor facilities from them to the farmers It was also due to unavailability of appropriate facilities for tenant farmers They were unable to avail the bank facilities due to unavailability of owned land Factor market risk also contained five market related variables which has positive relation with the factor Factor flood risk consists of five variables which were having high loadings greater than table Factor can be named as input cost because it contained four input related variables Cashlessness factor had a positive relationship with the variables like inadequate Government support including crop insurance, shortage of cash on hand and lack of savings Factor catastrophe had a high loading of four natural hazard related variables Land risk factor was having high loadings of land risk related variables

## Farmers perceptions towards Management strategies

Result of factor analysis on risk management strategies of upper, middle and lower Mahanadi region was presented in table IV, V and VI See Appendix Factor analysis obtained four factors from risk management strategies in all the three regions These factor loadings were greater than one eigenvalues explains about , and per cent of total variance for upper, middle and lower regions, respectively

Growing more than one variety of the same crop s was the most effective strategy, while selection of crop varieties with low price variability was the least effective strategy in the upper region Table IV, See Appendix In the middle region, growing more than one crop like paddy and green gram, paddy and black gram was considered as the most practiced risk management strategy and practicing lift bore well irrigation as the least important strategy Table V, See Appendix It can be clearly seen from Table VI See Appendix that crop diversification was the most influential risk management response for the lower Mahanadi region farmers, whereas government financial support was the least important management strategy

Table IV See Appendix represents the four obtained factors from the factor analysis in the upper region Those factors can be named as diversification, credit reserves, marketing and off farm activities Factor had high loadings of growing more than one variety of the same crop s, lift borewell irrigation, re cultivation of seedlings, using traditional flood resistance crop, pests and diseases control, hiring labour on need basis, crop diversification, cultivating in Rabi and Summer season instead of Kharif and growing more than one crop and named as diversification Factor was named as credit reserves as it contained with arrangement of money from friends and relatives, depending on precautionary saving, leasing assets rather than owning them, depending on MGNR GA, management of debt and dependent on government financial support Factor contained high loadings of four market risk management variables, hence, it was named as marketing Factor was summarised as Off farm activities because it was highly loaded with four off farm risk management strategy variables

Table V See Appendix represents the Varimax rotated factor loadings of risk management strategies for middle Mahanadi region It was clear from the table that factor diversification containing nine management strategies related to diversification, which were having highly loaded factor scores Factor was constructed as marketing as it contained with spreading sales over time by storing product through gathering market information, spreading sales among retailers and selection of crop varieties with relatively lower price variability Factor was highly loaded with credit risk management strategies and hence was named as credit reserves Factor had highly loaded with farmers working off farm in off seasons, farm activities diversification, family members working off farm activities and off farm investment

Result of factor analysis with mean values and factor loadings for the lower Mahanadi region is presented in table VI See Appendix Four factors have been obtained and named as diversification, credit reserves, marketing and off farm activities First factor named as diversification because it contained variables which are related to diversification Second factor was summarised as credit reserves because it contains six credit risk management strategies Third factor was constructed as

marketing which contains four market risk management variables. Factor four was named as off farm activities because it was having highly loaded off farm activities related variables.

## **Determinants of Risk sources and management strategies**

Multiple regression analysis was used to examine the relationship between socio economic variables, risk perceptions and management strategies. Regression analysis showed the relationship between farmers characteristics and perceptions on various sources of risks: credit, input cost, market risk, flood risk, production risk and cash lessness. Bardhan *et al*, Ahsan, I bal *et al*, Asravor,

The result of this regression for upper, middle and lower regions are shown in table , and , respectively. Further, table , and shows the relationship between risk management strategies and farm and farmers characteristics. Patrick and Musser, Flaten *et al*, Bardhan *et al*, Ahsan,

## **Perceptions of risk sources**

### **Upper region**

Results demonstrate that aged farmers perceived credit, input cost, market, flood and production risk to be relatively higher for their farming, whereas younger farmers considered cash lessness to be an important source of risk. Farmers belonging to ST and SC perceived credit, market and cash lessness risk as an important source of risk, whereas farmers belonging to General and OBC group considered input cost, flood and production risk as important. Similarly, farmers with higher education considered credit and input cost as important sources of risk, whereas illiterate farmers perceived market and flood risk as major source of risk. Table

Farmers who owned land considered input cost as the main source of risk, while landless farmers perceived credit and production risk as the major sources of risk. Farmers who depend on other farm activities like dairy and fishery perceived production and cashlessness as major sources of risk. Farmers with more earning members in the family considered input cost and flood risk as most important sources of risk. On the other hand, cashlessness was perceived as a major source of risk by the farmers who had fewer earning members. In this region, farmers mostly belonged to joint families. Families with more earning members had greater household incomes because family members who were not engaged in farm activities opt for other off farm activities like daily wage labourers, construction workers and shop keeping. Well trained and experienced farmers considered input cost and production risk as most important as compared to less experienced farmers. Farmers who depend more on off farm income perceived credit risk to be important while farmers who do not depend on off farm income perceived input cost, flood and cashlessness risk as major sources of risk.

Large farmers considered input cost as a major source of risk while small farmers identified credit, production and market risk as important sources of risk. Input cost risk was perceived less by the farmers who received loans from banks. Farmers who avail government support in the form of cash and kind perceived input cost, production and cashlessness risk to be less important. Distance from the market had a positive impact on cashlessness risk. Due to long distance of main market location, farmers of this region sold their product at lesser price. This further led to input output imbalances.

Farmers of this region perceived market risk to be relatively higher due to lack of information about the market shown in Table

**Table 2: Determinants of Risk Perceptions of Upper Region Farmers**

Socio-economic variables	Risk source factors					
	Credit	Input cost	Market	Flood	Production	Cash lessness
Farmer's age						
Social group						
Education						
Land ownership status						
Enterprise diversification						
Ratio of earning member to the household size						
Experience						
Off farm income						
Farm Size

F statistics						

Note:  $\alpha$ ,  $\beta$ ,  $\gamma$  indicates the significance level at  $\alpha$ ,  $\beta$  and  $\gamma$ , respectively

### Middle region

Results of the regression model table indicates that aged farmers perceived production, land and cashlessness as important sources of risk. Similarly, farmers belonging to ST and SC perceived production and credit risk as important. On the other hand, risk of market and input cost was perceived as frequent sources of risk for the General and OBC farmers. This is due to the imbalance in distribution of land among different social groups. Illiterate farmers perceived credit risk as the main factor of risk. This may be because they were unaware of the rules and regulations of bank credit facilities. Production, credit, land, input cost and cashlessness risks were perceived to be less risky by the farmers who have own land. Farmers who live in joint families face more land risk than others. This is because the earning members are more in number and the size of the land holding was relatively smaller. Input cost was perceived as less risky by the farmers who depend more on other farm activities, like dairy. Households having more earning members perceived cashlessness risk as less risky and land risk as high.

experienced farmers perceived production, input cost and cashlessness to be less risky, On the other hand, the less experienced farmer perceived credit, land and market risk to be high. Similarly, farmers with more off farm income perceived production, input cost, cashlessness, market and land risk to be low. Farmers with larger land size consider production and input cost risk as important, while the small land holders perceived credit and cashlessness risk as major sources of risk. Input cost was perceived as a major source of risk for farmers who cannot avail bank loan. Similarly, farmers with more outstanding loan in the bank perceived credit risk as most important. Farmers who received more government support in terms of cash and kind perceived cashlessness as less risky than the other farmers. Long distance of the main market from village has a positive relation with cashlessness and market risk. Similarly, farmers with proper market information tend to have perceived input cost and market risk to be less risky.

**Table 3: Determinants of Risk Perceptions of Middle Region Farmers**

Socio-economic variables	Risk source factors					
	Production	Credit	Input cost	Cashless	Market	Land risk
Farmer's age

Note: , , indicates the significance level at , and , respectively

## Lower region

Table presents the result of multiple regression for the lower region. The results were statistically significant at , and per cent level. It was clear from the table that age of the farmer had a negative impact on flood and land risk. It means that as the farmer's age increases, the perceptions about flood and land risk reduce significantly. Farmers belonging to ST and SC considered credit, input cost and land risk to be important sources of risk, whereas, general and OBC perceived flood and catastrophe to be riskier. Credit, input cost and cashlessness risks were perceived to be less by the farmers who were engaged in other farm activities like dairy and poultry, whereas, land risk was perceived as riskier factor for them. Households with more earning members perceived land risk as a very important source of risk, while market, flood, catastrophe and input cost risk were considered as less important. Most farmers of this region also live in joint families. Earning members also helped the farmer during farming period, which reduce the cost of cultivation. They also engage in other activities, which stabilise the economic condition, and, further, it helps the farmer in risk reductions.

Experienced farmers tend to perceive market, flood and catastrophic risk as important. Similarly, credit and land risks were perceived as less important for the farmers who have larger land holding. Farmers with more off farm income perceived credit, input cost, flood, cashless and land risk to be less risky. Farmers with larger farm size, perceived risks of market, flood and catastrophe to be most important in their farm business while the risk of credit, land and cashlessness are perceived as less important. Farmers with more outstanding loan in the banks perceived credit risk to be more. Similarly, farmers who received government support in terms of money or kind perceived cashlessness as less important. Distance from main market had a positive impact on market and cashlessness risks. Long distance of main market from villages increases the transportation cost as it reduces the income and increases cashlessness. Farmers with proper market information perceived market risk to be lesser than other risks. Level of education and bank loan are not significant in all the models.

**Table 4: Determinants of Risk Perceptions of Lower Region Farmers**

Note: \*, \*\*, \*\*\* indicates the significance level at 10%, 5% and 1%, respectively

Overall results show that the factors like age, education, earning member to the household size, off farm income, farm size and government subsidies have a significant impact on farmers' perceptions towards all risks in upper Mahanadi region. Farmers from middle region reported social group, land ownership status, land size, off farm income and market information as the important determinants of risk perception. Further, farmers from lower Mahanadi region considered social group, land ownership status, earning member to the household size, farm size and off farm income as the important factors which had a substantial effect on risk perceptions.

## Farmers Perceptions of Risk Management Strategies

### Upper region

The results of multiple regression for the upper Mahanadi region is presented in table 4. It can be clearly seen from the table that aged farmers from this region considered credit reserves and marketing as important strategies, whereas, off farm activities were considered as important strategy by the younger farmers. Farmers belonging to SC and ST group perceived off farm activities as an important strategy because farmers from the SC and ST groups hold relatively smaller land size, unequal distribution of land and credit reserves. Conversely, farmers from General and OBC group perceived diversification, marketing and credit reserves as important management strategies due to their financial

stability. Similarly, education has a significant relationship with diversification. Farmers with higher education will be having more knowledge and understanding about the new technologies and seeds and this will encourage them to take higher diversification decisions for better production.

Farmers with less owned land considered off farm activities as an essential mitigation strategy. Diversification, keeping more credit reserves, marketing management and depending on off farm activities were the commonly followed management strategies of the farmers who had a greater number of earning members in their families. More earning members in the family increases financial stability and it helps the farmers to adopt different new mitigation strategies. Farmers with higher experience perceived diversification and marketing as essential management strategy, while less experienced farmers considered accumulating more credit reserves as important strategy.

**Table 5: Determinants of Risk Management of Upper Region Farmers**

R <sub>Adj</sub>				
F statistics				

Note: \*, \*\*, \*\*\* symbolize the significance at 10%, 5% and 1% respectively.

Farmers with more off farm income considered credit reserve, marketing and off farm investment as an important strategy. Off farm income helped the farmer to increase credit reserves for future and to tackle market related risk like bearing transportation and storage cost. Similarly, diversification was being perceived as an important management strategy for large land holding farmers, whereas credit reserves and off farm activities are essential mitigation strategies for marginal and small farmers. Farmers with more outstanding loan in bank perceived off farm activities as

important management strategy. Government support like lift irrigation facilities in the upper Mahanadi region has encouraged farmers towards higher diversification such as hybrid paddy seeds. Further, this diversification helped the farmers to increase credit reserves. Distance from the market has a negative relationship with marketing. The farmers who were staying in distant villages from main market will tend to manage less market related risks. The variables like other farm activities, bank loan and market information had an insignificant relationship with all the risk management factors.

### **Middle region**

Table presents the results of multiple regression which shows the relationship between four risk management strategies and socio economic variables of middle Mahanadi region. Aged farmers perceive diversification as an important mitigation strategy while younger farmer consider marketing and off farm activities as crucial strategies. Similarly, diversification is considered as crucial mitigation strategy for the farmers belonging to the general and OBC category while SCs and STs consider credit reserves and off farm activities as important management strategies. Farmers belonging to general and OBC categories are more educated and have more knowledge about farming than the other two categories. This knowledge has helped them in diversification. Educated farmers perceived market risk as more important while illiterate farmers perceived credit reserves as more important. Farmers who own land in their name are more likely to view diversification as an important management strategy while partial land holders considered credit reserves and off farm activities as important strategies of mitigation. Diversification is perceived as less important by the dependant of other farm activities farmers. Similarly, families with more earning members perceived diversification, credit reserves, marketing and off farm activities as the most important management strategies. Experienced farmers tend to perceive credit reserves, marketing to be significantly more important than other management strategies.

Farmers with more off farm income are more likely to view diversification, credit reserves, marketing and off farm activities as essential management response. Similarly, larger farmers considered diversification as more relevant while small farmers perceived credit reserve as more relevant management strategies. Support from the government in terms of cash or kind have a significant positive impact on credit reserves of the farmers. On the other hand, distance of the main market from village has a negative relation with risk management. It implies that, as the distance of market increases the marketing management will become difficult for the farmers who stay in distant villages. Farmers who have proper market information perceive credit reserve and marketing as relevant management strategies. Bank loan and outstanding loan have insignificant relation with diversification, credit reserves, marketing and off farm activities.

Note:  $\alpha$ ,  $\beta$ ,  $\gamma$  indicates the significance level at  $\alpha$ ,  $\beta$ , and  $\gamma$ , respectively

### Lower region

Table 7 shows the relation between four risk management factors and socio-economic characteristics of lower Mahanadi region farmers. Result of the study suggested that younger farmers of the Lower Mahanadi region tend to perceive marketing as an important management strategy. SC and ST farmers considered off-farm activities as significantly important while general and OBC farmers of this region considered credit reserves as most effective management strategy. Similarly, farmers with higher education considered credit reserve as important management strategy. On the other hand, diversification and credit reserves were the important management strategies followed by the farmers who had larger land holdings whereas partnership farmers perceived marketing and off-farm activities as most important. Farmers who engaged more on other farm activities, like dairy and fishery, perceived credit reserve as important source of risk, while diversification and marketing were less important. Farmers with more earning members in family considered diversification, credit reserves, marketing and off-farm activities as important management responses. Experience in farming had a significant positive relationship with marketing management strategy. It indicates that market risk management strategies improve according to the years of experience of a farmer. Farmers with more off-farm income considered credit reserve and off-farm activities as most important, while farmers with no off-farm income considered diversification and marketing as the essential management strategies.

Diversification was perceived as an important management strategy by large farmers and marketing was considered as important strategy by small farmers

Loan from the bank for farming during requirements tends to help the farmer towards more diversification whereas more outstanding loan in bank reduces credit reserves and force them to engage more in off farm activities. Support from the government, in terms of cash and kind, encourages the farmers towards more diversification, whereas, other farmers perceived off farm activities as most important coping strategy. Long distance of village from main market will reduce the marketing management due to unavailability of proper transportation facilities. Similarly, credit reserves and marketing were perceived as more relevant management strategies by the farmers who have proper market information.

**Table 7: Determinants of Risk Management of Lower Region Farmers**

Note: \*, \*\*, \*\*\* indicates the significance at 10%, 5% and 1%, respectively

All the results from the three regions showed that the management strategies of the farmers in the upper region significant and highly affected by the socio economic factors such as social group, farm size ratio of earning member to the household size and off farm income. In the case of middle Mahanadi region, it was highly affected by family size followed by off farm income and age. Hence, management strategies of Lower region farmers were influenced by social group and land ownership status, other farm activities, earning member to the household size, farm size, outstanding loan and off

farm income. Social category plays a vital role in upper, middle and lower region farmers' decision making towards management strategies. Similarly, off farm income also has a significant impact on management decision making in all the three regions.

## **Conclusion**

The results showed that the most important sources of risk were drought for the upper Mahanadi region, inadequate government support including crop insurance for the middle Mahanadi region and flood for the lower Mahanadi region. Important risk management strategies followed by the farmers were growing more than one variety of the same crop specifically paddy for the upper Mahanadi region, growing more than one crop within the given land for the middle Mahanadi and crop diversification for the lower Mahanadi region.

Farmers' risk perceptions significantly affected by many socio-economic variables in all the three regions. The number of significant variables is high in lower and middle region than lower region. In upper Mahanadi river region farmers were highly affected by age, education, earning member to the household size, off farm income, farm size and government support. For middle region farmers, the important factors were social group, land ownership status, land size, off farm income and market information while for the lower Mahanadi region farmers it was social group, land ownership status, earning member to the household size, off farm income and farm size. In addition, regression results showed that the variables like social group, ratio of earning member to the household size, off farm income and farm size had significant impact on the management strategies of upper Mahanadi region farmers. In the middle Mahanadi region, the main management strategies were earning member to family size, off farm income and age. The variables like social group and land ownership status, other farm activities, earning member to the household size, off farm income, farm size and outstanding loan were highly impacting management strategies of the lower region farmers.

The results of this study indicate that irrespective of the regions, all the farmers in the sample were concerned about three important types of risk i.e. production risk, market risk and financial risks. However, farmers' risk perception varies significantly across the three study regions. Therefore, the government policies and programmes should be implemented differently in these three regions. The policy makers should frame policies according to the requirements of farmers and by observing their perception toward risks. Such policies and programmes will be beneficial for the farmers since it will encourage them in taking up more risks and make investments in agriculture without any constrain. The findings of this study also indicate that the government should take more initiative to educate the farmers, inform them about available government schemes through advertisement and provide them with better training programmes. Accessibility and affordability are still a concern among farmers in the context of credit. Therefore, farmers should be provided with suitable credit facilities. Better policies need to be framed that are more tenant friendly. There is a lack of market facilities and road connectivity for farmers. Therefore, such facilities should be provided to enable them to market their produce on time and directly without depending solely on intermediaries. At present, the compensation for crop loss is reported to be inadequate. Therefore, more compensation for crop loss should be

provided to the farmers. The findings of the study not only provide valuable insight to the government but also to the researchers by highlighting the key issues that require attention.

*Note* Likert type scale was used not at all important to extremely important

For maintaining smooth path of consumption and avoiding adverse effects of future income fluctuation, farmers keep some amount from their current income as precautionary reserves by consuming less in the current period called precautionary savings
